**Post-Operative Instructions**  
**Shoulder Arthroscopy, Decompression, and Biceps Tenodesis**

**Day of Surgery**

A. Relax. Diet as tolerated.  
B. Icing is important for the first 5-7 days post-op. While the post-op dressing is in place, icing should be done continuously. Once the dressing is removed on the first or second day, ice is applied for 20-minute periods 3-4 times per day. Care must be taken with icing to avoid frostbite. Alternatively, Cryocuff or Game-ready ice cuff can be used as per instructions.

*You will be contacted by East Coast Orthotics regarding an ice compression unit to be used after surgery. This helps with pain and swelling but typically is not covered by insurance. The cost is $200-300 for a 2-week rental. Alternatively, ice gel packs with a shoulder or knee sleeve can be provided by the hospital for a minimal charge.*

C. Pain medication as needed every 6 hours (refer to pain medication sheet)

**First and Second Post-Operative Day**

A. Continue Icing.  
B. Pain medications as needed

**Third Post-Operative Day**

A. You may remove surgical bandage and shower this evening. Apply 4”x4” (or similar size) waterproof bandages to these wounds prior to showering and when showering is complete apply fresh ones. You will need to follow this routine for 2 weeks after surgery.

**Physical Therapy**

A. Physical Therapy should begin within the first 10 days after surgery. Please call your preferred facility to make an appointment.

*Note: Your shoulder will be very swollen. It may take a week or longer for this to go away. It is also common to notice burning around the shoulder as the swelling resolves. If excessive bleeding occurs, please notify Dr. Jazrawi.*

Call our office @ 646-501-7223 option 4, option 2 to confirm your first postoperative visit, which is usually about 1-2 weeks after surgery. If you are experiencing any problems, please call our office or contact us via the internet at www.newyorkortho.com.
Rehabilitation Guidelines for Biceps Tenodesis

The shoulder has two primary joints. One part of the shoulder blade, called the glenoid fossa forms a flat, shallow surface. This is coupled with the humerus (shaped like a golf ball) to make up the joint. The glenoid labrum is a “ring” of cartilage that turns the flat surface of the glenoid into a slightly deeper socket, which is similar to resting a golf ball on a golf tee instead of a table top, providing more shoulder stability. Another part of the scapula, called the acromion, articulates with the clavicle (collar bone) to make the acromioclavicular (AC) joint.

The rotator cuff is a group of four muscles: the supraspinatus, infraspinatus, teres minor, and subscapularis. The rotator cuff tendons attach around the humeral head (ball) and connect the humerus to the scapula. The long head of the biceps originates from the top of the glenoid fossa and labrum (top of the golf tee). It then runs through a groove in the humerus (upper arm bone) to join the short head of the biceps and inserts on a bone in the forearm1 (See Figure 1). Because of its position, the long head of the biceps is also considered to be a secondary stabilizer of the shoulder joint.

The long head of the biceps is at risk of injury and degenerative changes due to its proximity to the rotator cuff and the acromion. Since the long head of the biceps can act as a secondary stabilizer of the shoulder, it is also subject to injury during high speed overhead movements; repetitive overhead movements; or forceful shoulder activities when the elbow is straight. Specific injuries may include inflammation and irritation of the bicep tendon itself; a problem with the bicep tendon in conjunction with one of the rotator cuff tendons; or detachment of part of the tendon from the attachment point (SLAP tear).1 Bicep tendon degeneration and/or tearing can cause significant shoulder discomfort and dysfunction (See Figure 2).

A biceps tenodesis is a surgical procedure which may be performed for treatment of severe symptoms involving the biceps tendon, including inflammation or partial tears. It may be performed in isolation or as part of a larger shoulder surgery, including surgery involving the rotator cuff. During the biceps tenodesis, the normal attachment of the biceps tendon on the shoulder socket (glenoid fossa) is cut and reattachment of the tendon is made on the humerus (upper arm bone). This takes the pressure off the biceps attachment and places the attachment below the actual shoulder joint.2 The goal is to eliminate the shoulder pain coming from the bicep tendon. Different techniques are used to perform a biceps tenodesis. The surgical techniques can be broken down in to two categories: soft tissue techniques and hardware fixation techniques. Both techniques are effective and chosen based on surgeon preference and patient indications.
Rehabilitation Protocol After Biceps Tenodesis

The primary soft tissue technique is the “open key hole procedure”. An open keyhole technique relocates the tendon within the groove in the humerus bone after cutting it from its original location in the shoulder.1 The procedure involves the proximal end (the portion closest to the tip from its original location in the shoulder) of the biceps tendon being rolled into a ball and then sutured together as a mass. A keyhole is made in the groove of the humerus, the tendon mass is then inserted into the keyhole and pulled downward so that the tendon mass is locked in place.3

The Pitt technique uses two needles to pierce the bicep tendon in opposite directions. Sutures are then threaded through the needles to make a suture. This procedure is repeated with the needle placement reversed to create a locking pattern of the sutures. A knot is used to secure the sutures to the transverse ligament in the shoulder instead of to the bone.4

The hardware fixation techniques include screw fixation or endobutton fixation. In the screw fixation the tendon is detached and then placed in a hole made at the top of the bicipital groove. Then an interference screw is placed over the tendon, in to the bone, to hold it in place. In the endobutton technique the released tendon is secured to a button, the button is then secured behind the bone by sliding it in to a smaller hole at the top of the bicipital groove. Imagine a drywall type anchor where the pressure is applied from the inside out.

Appropriate rehabilitation is vital to optimizing your outcome after surgery. The rehabilitation guidelines are tailored to the type of procedure performed, therefore below you will find rehabilitation guidelines for soft tissue fixation techniques and rehabilitation guidelines for hardware fixation techniques. The rehabilitation guidelines are presented in a criterion based progression. General time frames are given for reference to the average, but individual patients will progress at different rates depending on their age, associated injuries, pre-injury health status, rehabilitation compliance and injury severity. Specific time frames, restrictions and precautions may also be given to protect healing tissues and the surgical repair/reconstruction.

Figure 2b and Figure 2c Torn long head of bicep. The muscle has retracted toward the elbow
Rehabilitation Protocol After Biceps Tenodesis

### Phase I (Surgery to 4 weeks after surgery)

| Goal | Sling immobilization to be worn at all times for showering and rehab under guidance of PT  
| Range of Motion | PROM → AROM → AROM of elbow as tolerated without resistance (allows biceps tendon to heal into new insertion on the humerus without being stressed), AROM of shoulder (no restriction)  
| Therapeutic Exercises | Grip strengthening  

### Phase III (4 to 12 weeks following surgery)

| Goals | Discontinue sling immobilization  
| Range of Motion Exercises | Being AROM of elbow with passive stretching at end ranges to maintain/increase elbow/biceps flexibility  
| Therapeutic Exercises | Begin light isometrics with arm at side for rotator cuff and deltoid – can advance to bands as tolerated  

### Phase III (3 to 6 month following surgery)

| Range of Motion Exercises | Progress to full AROM of elbow without discomfort  
| Therapeutic Exercises | Continue and progress with Phase II exercises  

- Begin UE ergometer  
- Begin sport-specific rehabilitation  
- Return to throwing at 3 months  
- Throwing from a mound at 4.5 months  
- Return to sports at 6 months if approved

Rehabilitation Protocol: Biceps Tenodesis

Name: ___________________________________________ Date: ________

Diagnosis: ___________________________________________ Date of Surgery: __________

Phase I (Weeks 0-4)
• Sling immobilization to be worn at all times except for showering and rehab under guidance of PT
• Range of Motion – PROM → AAROM → AROM of elbow as tolerated without resistance (allows biceps tendon to heal into new insertion on the humerus without being stressed), AROM of shoulder (no restriction)
  o Goals: full passive flexion/extension at elbow and full shoulder AROM
  o Encourage pronation/supination without resistance
  o Grip strengthening
• Heat/Ice before and after PT sessions

Phase II (Weeks 4-12)
• Discontinue sling immobilization
• Range of Motion
  o Begin AROM of elbow with passive stretching at end ranges to maintain/increase elbow/biceps flexibility
• Therapeutic Exercise
  o Begin light isometrics with arm at side for rotator cuff and deltoid – can advance to bands as tolerated
  o Begin light resistive biceps strengthening at 8 weeks
• Modalities per PT discretion

Phase III (Months 3-6)
• Range of Motion – Progress to full AROM of elbow without discomfort
• Therapeutic Exercise
  o Continue and progress with Phase II exercises
  o Begin UE ergometer
  o Begin sport-specific rehabilitation
  o Return to throwing at 3 months
  o Throwing from a mound at 4.5 months
  o Return to sports at 6 months if approved
• Modalities per PT discretion
